1 Introduction

There is an unevenness in the way \LaTeX puts space around ellipses (\dots) in text mode. This package attempts to fix that bug, and this documentation offers an explanation of the bug and offers advice on how to use ellipses in your text. This document does not offer guidance on the use of ellipses in mathematical formulas or non-English language text.

The standard definition of \dots in \LaTeX takes the inter-word stretch for the current font and puts that amount of space in between three normal dots; it then also adds that amount of space after the final dot. The documentation of the \LaTeX code acknowledges that this is a ‘kludge’ in that the interword stretch is being used for a purpose it was not meant for. There is another problem with this definition, however: the extra space after the final dot of the ellipsis. There is always more space after the ellipsis than before it, so that it is not properly centered between the text on either side.

That extra space is there for a good reason. When the ellipsis is followed by another dot, as at the end of a sentence, it is important that all four dots should be evenly spaced, otherwise the final dot is much closer than the others and the result is hideous. The same holds true for commas, exclamation marks and other punctuation on the baseline. So the extra space is necessary when an ellipsis is followed by certain punctuation characters, and the bug consists in the fact that \LaTeX always adds it, regardless of what text follows.

This package implements a simple fix. It redefines the \texttt{\dots} and \texttt{\textellipsis} commands so that they can look ahead at the next character and change their behavior accordingly: if the next character is one of .;:?! the extra space is added, if not, no extra space is added (if you load a package that makes any of these characters active, you may want to reload this list; see the section below on see below on \texttt{\textellipsispunctuation} and compatibility). This particular list of punctuation marks was not chosen arbitrarily: it includes all marks with a dot on the baseline (or a comma, which is like a dot with a tail). These marks produce a series of four

\footnote{This document corresponds to ellipsis v1.7, dated 2020/5/22. Many thanks to Frank Mittelbach, who made numerous suggestions and bugfixes that greatly improved this package.}
dots which must be spaced evenly – no other punctuation mark would normally benefit from having the extra space added.

The solution can be brittle – for example, if you write `\dots{}`, then the extra space will *not* be added, since the braces come between the command and the dot; the result will be very ugly. The solution to this is to enter ellipses carefully and consistently in your source text. If you use ellipses as recommended below, then the potential problem of evenly spacing an ellipsis that comes immediately after a baseline punctuation mark does not arise, since that combination of characters will not normally be used.

There are two other packages, *lips* and *xellipsis*, that address the problem of text ellipses in *\LaTeX*. The former strictly follows the advice of the *Chicago Manual of Style* in putting full word spaces between the dots of the ellipsis, and does not provide the possibility of more a tightly set ellipsis like the normal *\LaTeX* default. It also imposes its own set of rules for the spacing before and after an ellipsis. The latter offers more flexibility, but also tends to prefer the Chicago/MLA style. The Chicago and MLA manuals are good guides for preparing a typescript that will be typeset by someone else; but for fine typography, they are they wrong authorities to follow.

Usage

Install the package and put `\usepackage{ellipsis}` in your preamble. As noted above, you should be consistent in the way you enter ellipses in your text. For English text, Bringhurst (loc. cit.) recommends putting a space before and after an ellipsis that appears between two words, but no space before an ellipsis that appears before a punctuation mark such as a period, comma, etc. Then there is the question of breaking or non-breaking space. I think it is odd to find an ellipsis at the beginning of a line, so normally I would enter text like this: `\textit{uh~~\ldots~, oh}.`
If setting text in narrow columns you may prefer to allow line breaks before the ellipsis as well as after. Before punctuation, you would enter ellipses without a space before or after, like so: one, two, three\dots, ten\dots. Note, however, that some publishers do not like to see an ellipsis combined with a period or comma, and would rather a simple ellipsis at the end of a sentence and so forth.

One problem with using the \dots command is that it does not take an argument. So there is no brace to terminate it, and if you want a space to follow the ellipsis, you need to take care that it does not disappear, and so to write it like this: \dots or \dots or \dots. If you forget to do this, the space will disappear, gobbled up by the macro. I frequently find myself making this mistake, so I have added another option to help with it. If you pass the option \xspace to \ellipsis.sty, an \xspace macro will be added after every \dots macro. See the \texttt{BTFX Companion} for full information on that package, but in short, it adds a space except when followed by certain punctuation characters (a superset of the \texttt{ellipsispunctuation} list mentioned above). So you automatically get space after the ellipsis, unless it is immediately followed by punctuation, even if you write it like this: one~\dots two. If there are a few places where you don’t want a space after \dots, then write it like this: \dots, and the space will be suppressed.

You may wish to redefine the command \texttt{\ellipsisgap}, which is the space between the dots of the ellipsis. If you do this, you must do it in your preamble, after the \texttt{usepackage} line. The default value is the interword stretch of the current font, which is the normal \LaTeX definition. If you are using a font other than Computer Modern and if you are obsessive, you might wish to examine the ellipsis that the font designer included in your font and recreate it by defining the \texttt{\ellipsisgap} to an appropriate value, like so:

\begin{verbatim}
\usepackage{ellipsis}
This value seems right for the native ellipsis in Adobe Caslon:
\renewcommand{\ellipsisgap}{0.1em}
\end{verbatim}

You should probably define this in font-size dependent units, such as the em. See Bringhurst (loc. cit.) for further thoughts on the construction of ellipses.

\section{Compatibility}

It was mentioned above that if certain punctuation characters are made active, it will interfere with the ability of this package to recognize them. One important example of that practice is in the French option of Babel, which makes certain ‘double punctuation’ characters active, in order to put a bit of space before them. In this particular case, however, you do \emph{not} want to redefine the \texttt{ellipsispunctuation} list to make this package aware of these characters. If you were to do so, extra kerning would be added after an ellipsis in addition to thin space before the following punctuation, resulting in about twice as much space as needed. If you leave the default value of \texttt{ellipsispunctuation}, then these active characters will not be
recognized, and no extra kern will be added. Instead, the ellipsis will be separated from any following double punctuation by a thin space. This may not be quite the same as the space between dots of the ellipsis, but it may be close enough that no one will notice the difference. In any case, that’s what French Babel does.

Whether Babel is here following some sophisticated French typographical rule, or it’s just a fudge, I don’t know. Because Babel French removes the extra space from after \dots, but only adds space before ‘double punctuation’, there is no space between an ellipsis and ‘single punctuation’, which looks ugly to my (non-French) eyes. In these cases, using \texttt{ellipsis.sty} will add the extra space whereas French Babel on its own does not. This may be the wrong thing to do; if you are typesetting a text in French, you should familiarize yourself with the relevant norms, and possibly refrain from using this package. If you are loading the French option of Babel because you are quoting French text in a document whose main language is not French, then you should not worry about these issues. Because French Babel wants to redefine \dots, you must load \texttt{ellipsis.sty} after Babel if you are using the French option (even if you have no French text in your document).

The Spanish option of Babel has its own way of setting an ellipsis, but it uses a different command (\ldots), so that doesn’t interfere with the working of this package.

4 Implementation

\texttt{\ellipsisgap} Set the amount of space to put between the dots of the ellipse. Defaults to the standard \LaTeX amount.
\begin{verbatim}
1 \newcommand{\ellipsisgap}{\fontdimen3\font}
2 \DeclareOption{chicago}{\renewcommand{\ellipsisgap}{\fontdimen2\font}}
\end{verbatim}

\texttt{\ellipsis@before} \texttt{\ellipsis@after} We provide the hooks \texttt{\ellipsis@before} and \texttt{\ellipsis@after} to allow the production of automatically bracketed ellipses.

The \texttt{mla} package option sets these so as to produce ellipses like this: \ldots

If you do this, you never want the extra space after the ellipsis, so we set \texttt{\ellipsis@alwayscentertrue}
\begin{verbatim}
3 \newcommand{\ellipsis@before}{\[
4 \newcommand{\ellipsis@after}{\]}
5 \newif{\ellipsis@alwayscenter}
6 \ellipsis@alwayscenterfalse
7 \DeclareOption{mla}{% 8 \renewcommand{\ellipsis@before}{\[
9 \renewcommand{\ellipsis@after}{\]}
10 \ellipsis@alwayscentertrue}
\end{verbatim}

\texttt{\ellipsis@xspace} Append \texttt{xspace} if the \texttt{xspace} option is set.
\begin{verbatim}
11 \newcommand{\ellipsis@xspace}{\}
12 \DeclareOption{xspace}{% 13 \renewcommand{\ellipsis@xspace}{\xspace}}
\end{verbatim}
\ProcessOptions{relax}
\RequirePackage{xspace}

\ellipsis@default This is the LaTeX default definition, which is necessary to use when punctuation such as .,:;?! follows.
\newcommand{\ellipsis@default}{% 
  \ellipsis@before .\kern\ellipsisgap .\kern\ellipsisgap .\@\kern\ellipsisgap \ellipsis@after\relax}

\ellipsis@centered This is our new ellipsis without the extra space after it.
\newcommand{\ellipsis@centered}{% 
  \ellipsis@before .\kern\ellipsisgap .\kern\ellipsisgap .\@ellipsis@after\relax}

\ellipsispunctuation Here we define the list of punctuation marks before which we want to put \ellipsis@spacing space. This may be redefined by the user if desired. If you load a package that changes the \catcode of a character in this list, such as a language package that makes one of them active, and you want the extra kerning to be added in front of those characters, then you must then explicitly reset the list. Otherwise the changed character will no longer be recognized. (quote from ltfntcmd.dtx) In such a case, just repeat the line below, substituting \renewcommand for \newcommand, and putting it after \begin{document}
\newcommand{\ellipsispunctuation{,.:;!?}}

\textellipsis This is the new definition for an ellipsis which looks ahead: if the next char is in \ellipsispunctuation use \default@ellipsis, else use our new \center@ellipsis.

  This is the auxiliary code that scans through the list of punctuation.
\def{\ellipsis@scan}{\expandafter{\ellipsis@scan@aux}\ellipsispunctuation{\ellipsis@delim}}
\def{\ellipsis@scan@aux #1\ellipsis@delim}{% 
  \let{\ellipsis@one=#1}\ellipsis@token\ellipsis@delim
  \ifx\ellipsis@two\ellipsis@one
  \ellipsis@default
  \else
  \ellipsis@centered
  \else
  \ellipsis@scan{\ellipsis@one \#2}\ellipsis@delim
  \fi}
\ifx\ellipsis@token\ellipsis@one
  \default@ellipsis
  \else
  \ellipsis@centered
  \else
  \ellipsis@scan\ellipsis@delim
  \fi

  Here is the macro that looks ahead at the next token, put it in \ellipsis@token, and invokes the code to scan for it in the punctuation list.
Here we redefine the standard \LaTeX command to use our new definition. (the \expandafter needs to be added to make lookahead work). The only reason this must be done at the beginning of the document is that the French option of Babel unpleasantly redefines \dots at the beginning of the document, and so we have to override it again – and this is true even if you never use any French text in your document. We need to throw an error in the case where French Babel is loaded after us, because its AtBeginDocument hook is about to clobber our definition of \dots.

\dots

An extra command: this may be useful for the rare time when you want an ellipsis in the very middle of a word or whenever you just want a small bit of space (the intra-ellipsis spacing) before and after the ellipsis.

\midwordellipsis
Change History

v1.0
General: Initial version

v1.1
General: Modelled definition of \textellipsis on xspace.sty,
added chicago option

v1.2
General: Added mla option,
removed hard-coded list of
punctuation in favor or a
configurable list

v1.3
General: Removed to make
\ellipsisspacing and
\ellipsispunctuation user
configurable. Changed
\ellipsisspacing from a
length to a command to make
em pick up the font size when
it is used, rather than when it
is defined

v1.4
General: Changed
\ellipsisspacing to
\ellipsisgap for readability,
added \relax to prevent
spaces from being gobbled.

v1.5
General: Added the xspace option

v1.6
General: Fixed incompatibility
with French Babel

v1.7
General: Fixed incompatibility
with amsmath; fixed fragile
command; fixed spacing when
\nofrenchspacing; all fixes
thanks to Frank Mittelbach.
Added ref to xellipsis package.
